

Creating and Using MATLAB Functions

Increasing Readability and Usability of Codes

What is a function, and when should I create one?

▶ **Examples of functions:**

- sin, exp, plot, find, +, ./, /

▶ **Functions Simplify a Program**

- Move code from one level to another
- Hide ugly details from the programmer

▶ **Use Functions when:**

- A series of steps are repeated multiple times
- A complicated procedure must be performed
 - eg. Solving a linear system

Properties of Functions

Function Workspace vs. MATLAB Workspace

▶ Scope

- Variables used within the function are *different* than those used elsewhere
- Function variables are only defined while the function is executing!!!

▶ Types of variables

- Local Variables (default)
 - Variables used within a function. These are completely separate from any variables defined elsewhere (other functions, main program, etc)
- Global Variables
 - These can be seen by all routines (functions) within a program
 - Use these cautiously!
- Persistent Variables
 - Retain their value after the function is exited

Argument Lists

Getting Variables in and out of Functions

- ▶ Order of arguments in function declaration and function call
 - Order is important, names are not
- ▶ Number of arguments
 - Using “nargin” and “nargout” in programs

Creating User-Defined Functions

The Syntax

- ▶ function **[result]**=**fun_name**(**arg₁**, **arg₂**, ... **arg_n**)
 - Function declaration
 - **result** 📎 output from the function
 - Could be several variables, i.e. [a,b,c] = fun_name(...)
 - **fun_name** 📎 name of the function
 - Should be the same as the file name
 - MATLAB doesn't actually use the function name
 - **arg₁**, **arg₂**, ... **arg_n** 📎 input parameters for the function
- ▶ **EXAMPLE:** Create a function to compute the factorial of a number.

Recursive Functions

▶ What is a recursive function?

- A function that calls itself
 - If some condition holds, then the function calls itself.
 - $f(f(f(f(x)))))$

▶ EXAMPLE: revisit the factorial function.

- Could we write this as a recursive function?
 - $f(x) = x * f(x-1), \quad \text{for } x > 2 \quad \Rightarrow \quad y = f(f(f(f(\dots f(x))))\dots)$
- Algorithm:
 - Input: number to compute factorial of (x)
 - If x is larger than 2, then
 - Save the result as $x * \text{factorial}(x-1)$
 - Otherwise, the result is equal to x!
 - Output: result

```
function y = recurFact(x)
```

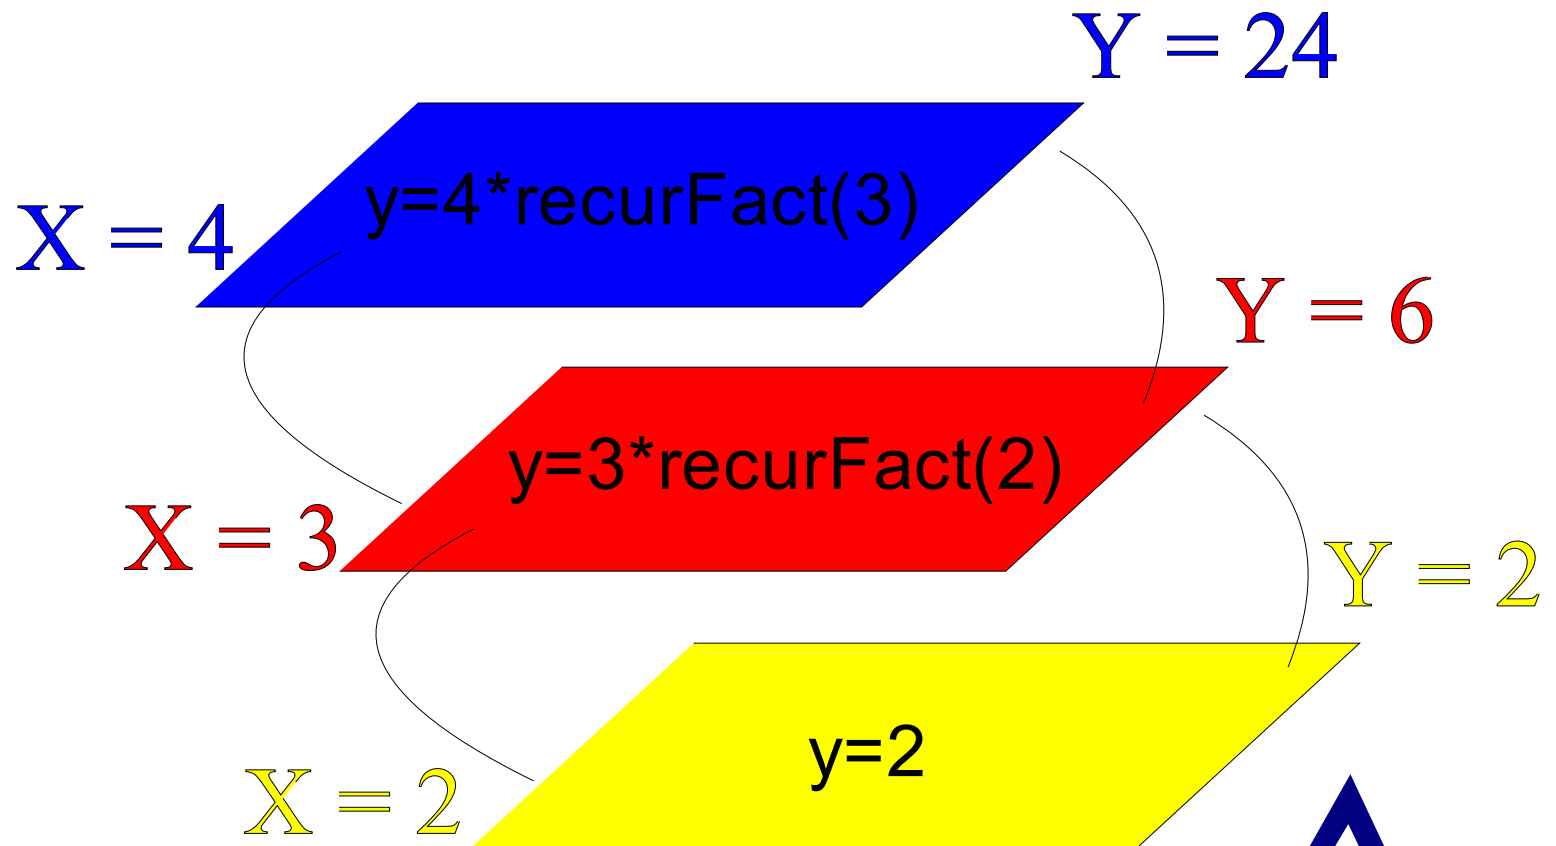

```
if (x > 2)
```

```
    y = x * recurFact(x-1);
```

```
else
```

```
    y = x;
```

```
end
```

Inline Functions

A Fast Way to Create Simple Functions

- ▶ `fun = inline('function', 'arg1', 'arg2', ...);`
 - Defines a function
 - `arg1...argn` are variables passed into this function
- ▶ **Example:**
`f=inline('a*x^2+b*x+c', 'a', 'b', 'c', 'x');`
`myNum = f(1,0,0,2);`
- ▶ More later...
